1.1 Model Definition

To define a model create a class based on model. Model.

The set_parameters() method must specify the space bounds as a list [[inf1,sup1] , [inf2,sup2], ...]. If a list of names is specified for certain variables, they can be accessed by name indexing (see varenv()). The parameters for which the name is not specified are called automatically var<n>. After the model initialization model.names will contain all the names.

```
>>> import model
>>> class MyModel(model.Model):
>>>

    def set_parameters(self):
        self.bounds = [[0,1], [0,1], [0,42]]
>>> self.names = ['A','mu','sigma']
```

The model can have other attributes. To add them override __init__(self) and make sure to call the parent __init__():

```
>>> def __init__(self,data):
>>> self.bounds = [[0,1], [0,1], [0,42]]
>>> self.names = ['A','mu','sigma']
>>> self.data = data
>>> super().__init__()
```

The logarithm of likelihood and prior have to be specified as class methods:

```
>>> ...
>>> def log_prior(self, x):
>>> return
```

The log_prior() and log_likelihood() methods must be capable to manage (*, space_dim)-shaped arrays and return a (*)-shaped array.

If names are not specified, all operations must be preformed over the last axis.

```
>>> def log_prior(self,x):
>>> return -0.5*np.sum(x**2, axis = -1)
```

If names are specified, it is possible to use model.Model.varenv():

```
>>> @model.Model.varenv
>>> def log_prior(self,x):
>>> return -(x['A'] - self.data[0])**2 - x['mu']**2
```

Finally, to automatically bound a function inside the model domain use the auto_bound() decorator:

```
>>> @model.Model.auto_bound
>>> @model.Model.varenv
>>> def log_prior(self,x):
>>> return -(x['A'] - self.data[0])**2 - x['mu']**2
```

```
Warning: varenv must be the first decorator applied
```

The data type used in the models is ['position', 'logL', 'logP']

```
>>> x['position']['A'][time,walker]
>>> x['logL'][time,walker]
```

in case it is necessary to reduce the data structure use numpy.lib.recfunctions.structured_to_unstructured.

1.2 Samplers usage

The available samplers are contained in samplers module. The first argument is a model. Model subclass instance. The second argument is the chain length.

```
>>> import sampler
>>> sampler = sampler.AIESampler(MyModel(), 500 , nwalkers=100)
```

To sample a function, define it as a log_prior and use sample_prior method of a Sampler subclass. After the chain is filled it is accessible as an attribute:

```
>>> x = sampler.chain
```

To join the chains of each particle after removing a burn in use:

```
>>> x = sampler.join_chains(burn_in = 0.3)
```

1.3 Nested Sampling usage

After having defined a model, create an instance of NestedSampling.NestedSampler specifying:

- 1. the model
- 2. the number of live points
- 3. the number of sampling steps the live points undergo before getting accepted

Other options are:

- npoints stops the computation after having generated a fixed number of points
- relative_precision
- load_old loads the save of the same run (if it exists). If filename is not specified, an *almost* unique code for the run is generated based on the features of the model and the NSampler run
- filename to specify a save file
- evo progress to display the progress bar for the evolutin process

The run is performed by ns.run(), after that every computed feature is stored as an attribute of the nested sampler:

1.4 Multiprocess Nested Sampling

It is performed by mpNestedSampler. The arguments are the same of NestedSampler.

Runs multiprocessing.cpu_count() copies of nested sampling, then merges them using the dynamic nested sampling merge algorithm.

After running, the instance contains the merged computed variables (logX, logZ, ecc.) and the single run variables through nested samplers attribute:

```
>>> mpns = mpNestedSampler(model_, nlive = 500, evosteps = 1200, load_old=False)
>>> mpns.run()
>>> print(f'Z = {mpns.Z} +- {mpns.Z_error})
>>> single_runs = mpns.nested_samplers
>>> for ns in single_runs:
>>> print(f'Z = {ns.Z} +- {ns.Z_error})
```

1.5 Diffusive Nested Sampling

It is performed by DiffusiveNestedSampler. The main parameters are the Model chain_length before a level is added, nlive of points the ensemble is made of and max_n_levels.

The resolution in prior mass can be adjusted specifying dns.Xratio after the sampler is initialised.

¹ https://arxiv.org/abs/1704.03459

1.6 Plotting

In stdplots are contained some shorthands for plotting the results for NS/mpNS/DNS runs.

1.6. Plotting

Generated code description

Code description generated automatically from docstrings.

2.1 Model

class model.Gaussian(dim=1)

__init__(dim=1)

Initialise and checks the model

class model.Model(*args)

Class to describe models

log_prior

the logarithm of the prior pdf

Type function

log_likelihood

the logarithm of the likelihood function

Type function

space_bounds

the coordinate of the two vertices of the hyperrectangle defining the bounds of the parameters

Type 2-tuple of np.ndarray

Note: The log_prior and log_likelihood functions are user defined and must have **one argument only**.

They also must be capable of managing (*,*, .., space_dimension)-shaped arrays, so make sure every operation is done on the **-1 axis of input** or use varenv().

If input is a single point of shape (space_dimension,) both the functions must return a float (not a (1,)-shaped array)

__init__(*args)

Initialise and checks the model

auto_bound()

Decorator to bound functions.

```
Parameters log_func (function) – A function for which self.log_func(x) is valid.
```

Returns the bounded function $log_func(x) + log_chi(x)$

Return type function

Example

```
>>> class MyModel(model.Model):
>>>
    @model.Model.auto_bound
>>> def log_prior(x):
>>> return x
```

is_inside_bounds(points)

Checks if a point is inside the space bounds.

Parameters points (np.ndarray) – point to be checked. Must have shape (*,space_dim,).

Returns

True if all the coordinates lie between bounds

False if at least one is outside.

Return type np.ndarray

log chi(points)

Logarithm of the characteristic function of the domain. Is equivalent to

```
>>> np.log(model.is_inside_bounds(point).astype(float))
```

Parameters points (np.ndarray) – point to be checked. Must have shape (*,space_dim,).

Returns

0 if all the coordinates lie between bounds

-np.inf if at least one is outside

Return type np.ndarray

varenv()

Helper function to index the variables by name inside user-defined functions.

Uses the names defined in the constructor of the model + var0,var1, ... for the one which are left unspecified.

```
Warning: When using with @auto_bound, it must be first:
>>> @auto_bound
>>> @varenv
>>> def f(self,x):
```

2.1. Model 6

class model.PhaseTransition(*args)

class model.Rosenbrock(*args)

class model.UniformJeffreys(*args)

2.2 Samplers

Module containing the samplers used in main calculations.

Since almost every sampler is defined by a markov chain, basic attributes are the model and the length of the chain.

Since is intended to be used in nested sampling, each sampler should support likelihood constrained prior sampling (LCPS).

class samplers.AIESampler(model, mcmc_length, nwalkers=10, space_scale=None, verbosity=0)

The Affine-Invariant Ensemble sampler (Goodman, Weare, 2010).

After a uniform initialisation step, for each particle k selects a pivot particle an then proposes

$$j = k + random(0 \rightarrow n)$$

$$z \sim g(z)$$

$$y = x_j + z(x_k - x_j)$$

and then executes a MH-acceptance over y (more information here²).

AIEStep (*Lthreshold=None*, *continuous=False*)

Single step of AIESampler.

Parameters

- Lthreshold (float, optional) The threshold of likelihood below which a point is set as impossible to reach
- **continuous** (bool, optional) If true use modular index assignment, overwriting past values as self.elapsed_time_index > self.length

__init__(model, mcmc_length, nwalkers=10, space_scale=None, verbosity=0)
Initialise the chain uniformly over the space bounds.

```
get_stretch(size=1)
```

Generates the stretch values given the scale_parameter a.

Output is distibuted as $\frac{1}{\sqrt{z}}$ in [1/a, a]. Uses inverse transform sampling

join_chains(burn_in=0.02)

Joins the chains for the ensemble after removing burn in % of each single_particle chain.

Parameters burn in (float, optional) – the burn in percentage.

Must be burn in > 0 and burn_in < 1.

2.2. Samplers 7

² https://msp.org/camcos/2010/5-1/camcos-v5-n1-p04-p.pdf

sample_prior(Lthreshold=None, progress=False)

Fills the chain by sampling the prior.

Class to override some functionalities of the sampler in case only the final state is of interest.

The main difference from AIESampler is that length and steps can be different

__init__ (model, steps, length=None, nwalkers=10, verbosity=0, space_scale=None)
Initialise the chain uniformly over the space bounds.

bring_over_threshold(logLthreshold)

Brings the sampler over threshold.

It is necessary to initialise the sampler before sampling over threshold.

Parameters Lthreshold (float) – the logarithm of the likelihood.

get_new(Lmin, start_ensemble=None, progress=False, allow_resize=True)

Returns nwalkers different point from prior given likelihood threshold.

As for AIEStep, needs that every point is in a valid region (the border is included).

If the length of the sampler is not enough to ensure that all points are different stretches it doubling self.steps each time. The stretch is *permanent*.

Parameters Lmin (float) – the threshold likelihood that a point must exceed to be accepted

Returns new generated points

Return type np.ndarray

class samplers.Sampler(model, mcmc_length, nwalkers, verbosity=0)

Produces samples from model.

It is intended as a base class that has to be further defined. For generality the attribute *nwalkers* is present, but it can be one for not ensamble-based samplers.

model

Model defined as the set of (log_prior, log_likelihood, bounds)

Type model.Model

mcmc_lenght

the lenght of the single markov chain

Type int

nwalkers

the number of walkers the ensamble is made of

Type int

__init__(model, mcmc_length, nwalkers, verbosity=0)
Initialise the chain uniformly over the space bounds.

2.2. Samplers

2.3 NestedSampling.py

The nested sampling module. In the first (and probably only) version it is mainly tailored onto the AIEsampler class, so there's no choice for the sampler.

```
class NestedSampling.NestedSampler(model,
                                                            nlive=1000,
                                                                             npoints=numpy.inf,
                                                                      relative_precision=0.0001,
                                               evosteps=150,
                                               load old=None,
                                                                                filename=None,
                                               evo_progress=True)
     Class performing nested sampling
     get ew samples()
          Generates equally weighted samples by accept/reject strategy.
     initialise()
          Initialises the evolver and Z value
     mean_over_t()
          Computes the mean and std of logZ and weights over t.
          The process of finding the worst among n values is simulated and the mean over N Z SAMPLES is
          computed.
     run()
          Performs nested sampling.
     update()
          Updates the value of Z given the current state.
          The number of live points is of the form:
          nlive,(jump) 2nlive-1, 2nlive-2, ..., nlive, (jump) 2nlive-1, ecc.
          Integration is performed between the two successive times at which N = nlive (extrema in-
          cluded), then one extremum is excluded when saving to self. N.
     varenv points()
          Gives usable fields to self.points['position'] based on model.names
NestedSampling.log_worst_t_among(N)
     Helper function to generate shrink factors
     Since max(\{t\}) with t in [0,1], len(\{t\}) = N is distributed as Nt^{**}(N-1), the cumulative function is y = N
     t**(N) and sampling uniformly over y gives the desired sample.
     Therefore, max(\{t\}) is equivalent to (unif)^{**}(1/N)
     and log(unif^{**}(1/N)) = 1/N*log(unif)
class NestedSampling.mpNestedSampler(*args, **kwargs)
     Multiprocess version of nested sampling.
     Runs multiprocess.cpu count() instances of NestedSampler and joins them.
     logX
               Type np.ndarray(dtype=np.float64)
     logL
               Type np.ndarray(dtype=np.float64)
     N
               Type np.ndarray(dtype=np.int)
```

```
logZ
         Type np.float64
Z
         Type np.float64
logZ error
         Type np.float64
Z_error
         Type np.float64
logZ samples
         Type np.ndarray(dtype=np.float64)
nested_samplers
    The individual runs. Each nested sampler has completely defined attributes.
         Type list of NestedSampler
run time
    The time required to perform the runs and merge them.
         Type np.float64
error estimate time
    The time required to perform error estimate on logZ
         Type np.float64
how_many_at_given_logL(N, logLs, givenlogL)
    Helper function that does what the name says.
    See dynamic nested sampling<sup>3</sup>.
merge all()
    Merges all the runs
param_stats()
    Estimates the mean and standard deviation of the parameters
run()
    Performs nested sampling.
```

2.4 DiffusiveNestedSampling.py

class DiffusiveNestedSampling.DiffusiveNestedSampler(model,

max_n_levels=100, nlive=100, chain_length=1000)

G()

Theorethical cumulative density function for X, given that X is smaller than the last level. see conceptual_notes.

³ https://arxiv.org/abs/1704.03459

continue_exploration()

Continues the exploration using uniform weighting.

```
revise_X(points_logL)
```

Revises the X values of the levels.

Parameters points_logL (np.ndarray) – the points generated while sampling the mixture

run()

Runs the code

An AIE sampler for mixtures of pdf.

It is really problem-specific, forked from AIESampler class because of the great conceptual differences.

```
AIEStep(continuous=False, uniform weights=False)
```

Single step of mixtureAIESampler. Overrides the parent class method.

Parameters

- **continuous** (bool, optional) If true use modular index assignment, overwriting past values as self.elapsed time index > self.length
- uniform_weights (bool, optional) If True sets uniform weighting between levels instead of exponential.

Note: The difference between the AIEStep function of AIESampler is that every single-particle distribution is chosen randomly between the ones in the mixture.

This is equivalent to choosing a logL_threshold and rejecting a proposal point if its logL < logL_threshold

```
sample prior(progress=False, **kwargs)
```

Fills the chain by sampling the mixture.

Parameters

- **progress** (bool) Displays a progress bar. Default: False
- **uniform_weights** (bool, optional) If True sets uniform weighting between levels instead of exponential.

2.5 stdplots.py

```
standard plots module
```

```
stdplots.XLplot(NS, fig_ax=None)
```

Does the (logX, logL) plot.

Parameters NS (NS/mpNS/DNS sampler) -

stdplots.hist_points(NS)

Plots the histogram of the equally weighted points

Parameters NS (NS/mpNS sampler) -

2.5. stdplots.py

```
stdplots.scat(NS, fig_ax=None)
```

Does a 2D scatter plot.

Parameters NS (NS/mpNS sampler) -

stdplots.scat3D(NS)

Does a 3D scatter plot (x,y,L).

Parameters NS (NS/mpNS sampler) -

stdplots.weightscat(NS, fig_ax=None)

Does a 2D scatter plot using a colormap to display weighting.

Parameters NS (NS/mpNS sampler) -

2.6 Utility routines

utils.hms(secs)

Returns time in hour minute seconds from at given time in seconds.

utils.logsubexp(x1, x2)

Helper function to execute $\log (e^{x_1} - e^{x_2})$

Parameters

- x1 (float) -
- x2 (float) -

utils.logsumexp(arg)

Utility to sum over log_values. Given a vector [a1,a2,a3, ...] returns $\log(e^{a1} + e^{a2} + ...)$

Parameters arg (np.ndarray) – the array of values to be log-sum-exponentiated

Returns $\log (e^{a1} + e^{a2} + ...)$

Return type float

2.6. Utility routines
